## 1 Groups

### 1.1 B

Prove Lagrange's theorem for orders in the special case that  $G$  is a finite abelian group.

### 1.1.1 Proof

Let  $G = \{g_1, g_2, g_3, \dots, g_n\}$  and Let  $g \in G$ . Let  $h = g_1 g_2 g_3 \dots g_n$ . The map  $x \mapsto gx$  is a bijection, so  $h = gg_1 gg_2 gg_3 \dots gg_n$  for some permutation of  $g_i$ . However, because  $G$  is abelian  $h$  is the same no matter the permutation. Then, we can simplify this to  $h = g^n h$  therefore  $g^n$  is the identity.

## 1.2 D

Let  $p$  be a prime. Show that the only group of order  $p$  is  $\mathbb{Z}/p\mathbb{Z}$ .

### 1.2.1 Proof

Let  $G$  be a group with order  $p$ . Let  $0$  be the identity element.  $p$  is prime, so  $p \geq 2$ , which means there must be at least one other element  $g$  which is not the identity element. Let  $H$  be the subgroup generated by  $g$ . If  $|H| = |G|$ , then we are done through the map  $n \mapsto g^n$ .

Assume then that  $|H| \neq |G|$ .  $|H|$  has to be smaller than  $|G|$ , because otherwise  $G$  is not closed. By Lagrange's theorem,  $g^{|H|} = 0$ , and  $g^{|G|} = 0$ , so  $g^{k|H| \bmod |G|} = 0$ , for  $k \in \mathbb{N}$ .

$(\mathbb{Z}/p\mathbb{Z})^\times$  is a group with size  $p - 1$ , so therefore by Lagrange's theorem, for any  $x \in (\mathbb{Z}/p\mathbb{Z})^\times$ ,

$$x^{p-1} = 1 \pmod{p} \quad (1)$$

Equation 1 is Fermat's little theorem. Since we know  $|G|$  is prime, by Fermat's Little theorem,  $|H|^{|G|-1} \bmod |G| = 1$ ,

so  $g = 0$ , but we said that  $g$  was not the identity, so  $|H| = |G|$ , and they are isomorphic.

## 1.3 H

Let  $p$  be a prime and  $F_1 = F_2 = 1, F_{n+2} = F_{n+1} + F_n$  be the Fibonacci sequence. Show that  $F_{2p(p^2-1)}$  is divisible by  $p$ .

### 1.3.1 Proof

We can turn the fibonacci sequence into a matrix using

$$g = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \quad (2)$$

because

$$\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}^n = \begin{pmatrix} F_{n+1} & F_n \\ F_n & F_{n-1} \end{pmatrix} \quad (3)$$

This is proved using induction. The base case is  $n = 1$  and is true, then

$$g^{n+1} = gg^n = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} F_{n+1} & F_n \\ F_n & F_{n-1} \end{pmatrix} = \begin{pmatrix} F_{n+2} & F_{n+1} \\ F_{n+1} & F_n \end{pmatrix} \quad (4)$$

If the field of the matrix is  $\mathbb{Z}/p\mathbb{Z}$ , and we prove that  $g^n = I$ , where  $I$  is the identity matrix, then we will have shown that  $F_n = 0 \pmod{p}$ .

Observe that the determinant of  $g$  is  $-1$ . Note that the set of all 2 by 2 matrices mod  $p$  with determinant  $\pm 1$  forms a group. It has an identity element, matrix multiplication is associative, and the inverse of each matrix also has the determinant  $\pm 1$ .

Let this group be  $G$ . Then all elements of this group are forms of  $ad - bc = \pm 1$ ,  $a, b, c, d$  greater than equal 0 and less than  $p$ . If we can show that  $|G| = 2p(p^2 - 1)$ , then by Lagrange's theorem,  $g^{|G|} = I$ , completing the proof.

For now consider forms of  $ad - bc = 1$ . For any value  $ad$ , there exists a unique value that  $bc$  must be to satisfy the equation.

Split this into cases where  $ad = 1$  and  $ad \neq 1$

**case 1** If  $ad = 1 \pmod{p}$ , then both  $a$  and  $d$  cannot be 0, and if  $a$  is non zero then there is a unique value that  $d$  must be, so there are  $p - 1$  pairs of  $a, d$  that satisfy  $ad = 1 \pmod{p}$ . Then  $bc = 0 \pmod{p}$ , so  $b$  or  $c$  must be 0, so there are  $2p - 1$  pairs of  $b, c$ , that satisfy this. Therefore, there are  $(p - 1)(2p - 1)$  total.

**case 2:** If  $ad \neq 1$ , then of the  $p^2$  total pairs of  $a, d$ , we subtract those that have  $ad = 1$ , leaving us with  $p^2 - p + 1$  pairs. By the same reason that there are  $p - 1$  pairs that satisfy  $ad = 1$ , there are  $p - 1$  pairs of  $b, c$  that will satisfy  $bc = 1 - ad$ , leaving  $(p^2 - p + 1)(p - 1)$  total.

Combining the cases, we get  $(p - 1)(p^2 + p)$  matrices that have determinant 1. By a similar proof, we can show there are  $(p - 1)(p^2 + p)$  matrices that have determinant  $-1$ . In total there are  $2(p - 1)(p^2 + p) = 2p(p^2 - 1)$ , so  $|G| = 2p(p^2 - 1)$ , which completes the proof.

## 2 Metric Spaces

### 2.1 Exercise 2.3.4

Show that  $\epsilon - \delta$  continuity implies sequential continuity at each point.

### 2.1.1 Proof

Let  $p$  be the continuous point for  $f$ .

It is needs to be shown that  $x_1, x_2, \dots$  is a sequene in  $M$  is covering to  $p$ , then the sequence,  $f(x_1), f(x_2), f(x_3), \dots$  covergences to  $f(p)$

To show convergence for  $f(x_1), f(x_2), f(x_3), \dots$  covergences to  $f(p)$ , given any  $\varepsilon$ , it needs to be shown that there exists a positive integer  $A$ , such that for any  $a > A$ ,  $d(f(x_a), f(p)) < \varepsilon$ .

Since  $\varepsilon - \delta$  continuity is assumed, that means that there is a  $\delta$  such that

$$d(x, p) < \delta \Rightarrow d(f(x), f(p)) < \varepsilon \quad (5)$$

Because  $x_1, x_2, x_3, \dots$  converges, it menas that there is an integer  $A$  such that for any  $a > A$ ,  $d(x_a, p) < \delta$ , but by equation 5, this means that  $d(f(x_a), f(p)) < \varepsilon$ , and so this concludes the proof.

## 3 Homomorphism and Quotient Groups

### 3.1 A

Determine all groups  $G$  for which the map  $\phi : G \rightarrow G$  defined by

$$\phi(g) = g^2 \quad (6)$$

is a homomorphism.

### 3.1.1 Proof

By definiton of homomorphism, for any  $g_1, g_2$ ,  $\phi(g_1 g_2) = \phi(g_1) \phi(g_2)$ , so  $(g_1 g_2)^2 = g_1^2 g_2^2$ , so  $g_1 g_2 g_1 g_2 = g_1 g_1 g_2 g_2$  so  $g_2 g_1 = g_1 g_2$ , Therefore, these groups are abelian.

### 3.2 C

Does  $S_4$  have a normal subgroup of order 3?

### 3.2.1 Answer

Yes, take the element that maps  $(1, 2, 3, 4$  to  $(1, 3, 4, 2)$ . Then the subgroup  $H$  generated by this element consists of  $(1, 2, 3, 4), (1, 3, 4, 2), (1, 4, 2, 3)$

Let  $g$  map to a permutation  $x_1, x_2, x_3, x_4$ , we must show that  $ghg^{-1} \in H$ . Enumerate  $h$ , if  $h$  is identity, it is trivial. If  $h = (1, 3, 4, 2)$ , then  $ghg^{-1} = (1, 4, 2, 3)$

$$\begin{array}{l}
 (1,2,3,4) \ (4,3,2,1) \\
 gh = (4,2,1,3) \ ghg^{-1} = (3,1,2,4) \\
 ghg^{-1}
 \end{array}$$
