1 Groups

1.1 B

Prove Lagrange's theorem for orders in the special case that G is a finite abelian group.

1.1.1 Proof

Let $G = \{g_1, g_2, g_3, \dots, g_n\}$ and Let $g \in G$. Let $h = g_1 g_2 g_3 \dots g_n$. The map $x \mapsto gx$ is a bijection, so $h = gg_1 gg_2 gg_3 \dots gg_n$ for some permutation of g_i . However, because G is abelian h is the same no matter the permutation. Then, we can simplify this to $h = g^n h$ therefore g^n is the identity.

1.2 D

Let p be a prime. Show that the only group of order p is $\mathbb{Z}/p\mathbb{Z}$.

1.2.1 Proof

Let G be a group with order p . Let 0 be the identity element. p is prime, so $p \geq 2$, which means there must be at least one other element g which is not the identity element. Let H be the subgroup generated by g . If $|H| = |G|$, then we are done through the map $n \mapsto g^n$.

Assume then that $|H| \neq |G|$. $|H|$ has to be smaller than $|G|$, because otherwise G is not closed. By Lagrange's theorem, $g^{|H|} = 0$, and $g^{|G|} = 0$, so $g^{k|H| \bmod |G|} = 0$, for $k \in \mathbb{N}$.

$(\mathbb{Z}/p\mathbb{Z})^\times$ is a group with size $p - 1$, so therefore by Lagrange's theorem, for any $x \in (\mathbb{Z}/p\mathbb{Z})^\times$,

$$x^{p-1} = 1 \pmod{p} \quad (1)$$

Equation 1 is Fermat's little theorem. Since we know $|G|$ is prime, by Fermat's Little theorem, $|H|^{|G|-1} \bmod |G| = 1$,

so $g = 0$, but we said that g was not the identity, so $|H| = |G|$, and they are isomorphic.

1.3 H

Let p be a prime and $F_1 = F_2 = 1, F_{n+2} = F_{n+1} + F_n$ be the Fibonacci sequence. Show that $F_{2p(p^2-1)}$ is divisible by p .

1.3.1 Proof

We can turn the fibonacci sequence into a matrix using

$$g = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \quad (2)$$

because

$$\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}^n = \begin{pmatrix} F_{n+1} & F_n \\ F_n & F_{n-1} \end{pmatrix} \quad (3)$$

This is proved using induction. The base case is $n = 1$ and is true, then

$$g^{n+1} = gg^n = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} F_{n+1} & F_n \\ F_n & F_{n-1} \end{pmatrix} = \begin{pmatrix} F_{n+2} & F_{n+1} \\ F_{n+1} & F_n \end{pmatrix} \quad (4)$$

If the field of the matrix is $\mathbb{Z}/p\mathbb{Z}$, and we prove that $g^n = I$, where I is the identity matrix, then we will have shown that $F_n = 0 \pmod{p}$.

Observe that the determinant of g is -1 . Note that the set of all 2 by 2 matrices mod p with determinant ± 1 forms a group. It has an identity element, matrix multiplication is associative, and the inverse of each matrix also has the determinant ± 1 .

Let this group be G . Then all elements of this group are forms of $ad - bc = \pm 1$, a, b, c, d greater than equal 0 and less than p . If we can show that $|G| = 2p(p^2 - 1)$, then by Lagrange's theorem, $g^{|G|} = I$, completing the proof.

For now consider forms of $ad - bc = 1$. For any value ad , there exists a unique value that bc must be to satisfy the equation.

Split this into cases where $ad = 1$ and $ad \neq 1$

case 1 If $ad = 1 \pmod{p}$, then both a and d cannot be 0, and if a is non zero then there is a unique value that d must be, so there are $p - 1$ pairs of a, d that satisfy $ad = 1 \pmod{p}$. Then $bc = 0 \pmod{p}$, so b or c must be 0, so there are $2p - 1$ pairs of b, c , that satisfy this. Therefore, there are $(p - 1)(2p - 1)$ total.

case 2: If $ad \neq 1$, then of the p^2 total pairs of a, d , we subtract those that have $ad = 1$, leaving us with $p^2 - p + 1$ pairs. By the same reason that there are $p - 1$ pairs that satisfy $ad = 1$, there are $p - 1$ pairs of b, c that will satisfy $bc = 1 - ad$, leaving $(p^2 - p + 1)(p - 1)$ total.

Combining the cases, we get $(p - 1)(p^2 + p)$ matrices that have determinant 1. By a similar proof, we can show there are $(p - 1)(p^2 + p)$ matrices that have determinant -1 . In total there are $2(p - 1)(p^2 + p) = 2p(p^2 - 1)$, so $|G| = 2p(p^2 - 1)$, which completes the proof.

2 Metric Spaces

2.1 Exercise 2.3.4

Show that $\varepsilon - \delta$ continuity implies sequential continuity at each point.

2.1.1 Proof

Let p be the continuous point for f .

It needs to be shown that x_1, x_2, \dots is a sequence in M is converging to p , then the sequence, $f(x_1), f(x_2), f(x_3), \dots$ converges to $f(p)$

To show $f(x_1), f(x_2), f(x_3), \dots$ converges to $f(p)$, given any ε , it needs to be shown that there exists a positive integer A , such that for any $a > A$, $d(f(x_a), f(p)) < \varepsilon$.

Since $\varepsilon - \delta$ continuity is assumed, that means that there is a δ such that

$$d(x, p) < \delta \Rightarrow d(f(x), f(p)) < \varepsilon \quad (5)$$

Because x_1, x_2, x_3, \dots converges, it means that there is a positive integer A such that for any $a > A$, $d(x_a, p) < \delta$, and by equation 5, this means that $d(f(x_a), f(p)) < \varepsilon$, and so this concludes the proof.

2.2 A

Let $M = (M, d)$ be a metric space, Show that

$$d : M \times M \rightarrow \mathbb{R} \quad (6)$$

is a continuous function.

2.2.1 Proof

Let (x, y) be a point in $M \times M$. Let x_1, x_2, x_3, \dots sequence that converges to x in M and similarly y_1, y_2, y_3, \dots is sequence that converges to y , then $(x_1, y_1), (x_2, y_2), (x_3, y_3), \dots$ converges to (x, y) , it needs to be shown that $d(x_1, y_1), d(x_2, y_2), d(x_3, y_3), \dots$ converges to $d(x, y)$

Let ε be a positive real, it needs to be shown that there exists a positive integer N such that for $n > N$ $|d(x, y) - d(x_n, y_n)| < \varepsilon$. As both x_1, x_2, x_3, \dots and y_1, y_2, y_3, \dots both converge, let N_1 be the value such that any $n > N_1$, $d(x_n, x) < \varepsilon/2$ and N_2 be the value such that $n > N_2$, $d(y_n, y) < \varepsilon/2$

Let N be the max of N_1, N_2 , and let $n > N$. Note that since absolute value itself obeys triangle inequality $|d(x, y) - d(x_n, y_n)| < |d(x, y) - d(x, y_n)| + |d(x, y_n) - d(x_n, y_n)|$. By triangle inequality, $|d(x, y) - d(x, y_n)| < d(y, y_n)$ and similarly $|d(x, y_n) - d(x_n, y_n)| < d(x, x_n)$, then $|d(x, y) - d(x_n, y_n)| < |d(x, y) - d(x, y_n)| + |d(x, y_n) - d(x_n, y_n)| < d(y, y_n) + d(x, x_n) < \varepsilon/2 + \varepsilon/2 = \varepsilon$, and this concludes the proof.

3 Homomorphism and Quotient Groups

3.1 A

Determine all groups G for which the map $\phi : G \rightarrow G$ defined by

$$\phi(g) = g^2 \tag{7}$$

is a homomorphism.

3.1.1 Proof

By definition of homomorphism, for any g_1, g_2 , $\phi(g_1g_2) = \phi(g_1)\phi(g_2)$, so $(g_1g_2)^2 = g_1^2g_2^2$, so $g_1g_2g_1g_2 = g_1g_1g_2g_2$ so $g_2g_1 = g_1g_2$. Therefore, these groups are abelian.

3.2 C

Does S_4 have a normal subgroup of order 3?

3.2.1 Answer

No.
